Parameter explanation

Nominal values

Nominal value

Value of a variable (e.g. voltage, current, resistance ...) according to which a motor, blower, or pump, or its characteristics and parts are specified or according to which they are designed.

Power consumption P_1

$$P_1 = U \cdot I$$

P_1 Power consumption in W

U Voltage in V

I Current in A

Output power P_2

For motors the output power P_2 is always given.

$$P_2 = 2 \cdot \frac{\pi}{60} \cdot M \cdot n$$

P_2 Output power in W

M Torque in Nm

n Rotational speed in min^{-1}

Efficiency η

Efficiency refers to the relationship between mechanical output P_2 and electrical power input P_1 .

$$\eta_2 = \frac{P_2}{P_1}$$

Example

Theoretically, a nominal voltage of 24 V and a rated current of 35 A result in a power input of P_1 :

$$P_1 = U_N \cdot I_N; P_1 = 24 \text{ V} \cdot 35 \text{ A}; P_1 = 840 \text{ W}.$$

This power consumption P_1 and the output P_{2N} (see Fig. page 7) determined from the characteristic-curves chart are used to calculate the efficiency η :

$$\eta = \frac{P_{2N}}{P_1} = \frac{636 \text{ W}}{840 \text{ W}} = 0,76 = 76\%$$

Rated torque M_N

The motor's rated torque is calculated from:

$$M_N = \frac{60}{2\pi} \cdot \frac{P_{2N}}{n_N}$$

M_N Rated torque in Nm

P_{2N} Rated power output in W

n_N Rated speed in min^{-1}

Rated speed n_N

Rated speed refers to the speed of a motor supplied with rated voltage and driven at a rated output.

Direction of rotation

When looking at the motor's shaft end, clockwise operation is deemed to be right-handed rotation.

For motors with two shaft ends, the shaft end opposite the commutator determines the direction of rotation.

Short-circuit values

The current consumed by the motor in case of short-circuit (when armature is braked to standstill), is the maximum current I_{max} .

When a short circuit occurs, the maximum torque M_A (breakaway torque) is effective.

IP degrees of protection

Valid for electrical equipment of road vehicles as under IEC 60529 and DIN 40050, Part 9.

- protection of electrical equipment within housing against influence of solid foreign bodies including dust
- protection of electrical equipment within housing against ingress of water
- protection of people against touching of moving mechanical parts within housing

Fastening

- housing fastening: By means of screws on the motor or transmission housing. Blowers are fastened in a similar manner, either to the drive motor or the air shroud
- flange mounting: The motor's drive-end support has a two or three-hole flange, or the front side contains three or four threaded holes for fastening

Cooling

- internal natural cooling: open-type design, without fan
- internal natural cooling: open-type design, with separate fan
- internal forced-air cooling: open-type design, with externally-driven fan
- surface natural cooling: closed design, without fan
- surface natural cooling: closed design, with separate fan

IP-code structure

If an index number is not given, then the letter "X" must be substituted (i.e. "XX", if both index numbers are missing). Additional and/or supplementary letters can be omitted without any substitution:

²⁾ The supplementary letter "K" is placed either immediately after the first index numbers 5 and 6 or immediately after the second index numbers 4, 6 and 9.

³⁾ During the water test for example: IP16KB protection against ingress of solid foreign bodies with a diameter ≥ 50 mm, protection against powerful spray water at high pressure, protection against being touched by fingers.

Explanations of IP code

Operating modes (VDE 0530)

Continuous operation S 1

Operation with constant load condition, the duration of which is sufficient to reach the thermal steady-state condition.

Parameters for curve inspection

- P_1 Power input
- P_V Power loss
- ϑ Temperature
- $\vartheta_{\max}$ Highest temperature
- t_B Load period
- t_r Relative on period (as percentage)
- t_S Duration
- t_{St} Standstill period

Short-term operation S 2

Operation with constant load condition, which does not last long enough however to enable the thermal steady-state condition to be reached, and a subsequent pause, which lasts long enough for the motor temperature not to deviate more than 2 K from the coolant temperature.

Example: S 2 – 60 min
(The stated time refers to 60 minutes of operation at normal rating)

Intermittent operation S 3

Operation, comprised of a sequence of similar cycles, each of which encompasses a time with constant load and a pause, whereby the startup current does not exert any perceptible influence on heating.

Example: S 3 – 10 %
(Stated percentage refers to on period)

Characteristic curves

With a specified working point of 160 Ncm one plots a vertical line to the torque axis. The intersecting points of these vertical lines with the various characteristic curves result in the operating data for the rated speed n_N , rated current I_N and mechanical output P_{2N} .

Explanation of characteristic curve evaluation

AP Working point

M Torque

P_2 Power output

I Current

n Rotational speed

Example:

Given: $M_N = 160 \text{ Ncm}$

Found: $n_N = 3.800 \text{ rpm (min}^{-1}\text{)}$

$P_{2N} = 636 \text{ W}$ and $I_N = 35 \text{ A}$

Motors with Hall sensor

Hall effect

If a current I_S flows through a chip, a Hall voltage U_H is generated transverse to the direction of the current, the size of which is proportional to the magnetic induction B (vertical to I_S) and the current I_S . The Hall voltage U_H is made up of:

$$U_H = R_H \cdot \frac{I_S \cdot B}{d}$$

R_H Hall-constant factor

Since the resulting Hall voltages are extremely small, they are amplified. When using silicon Hall elements, the circuit for signal processing (e.g. a Schmitt trigger with subsequent driver) are integrated directly onto the same chip. This component is then designated a Hall-IC. The output is a transistor with open collector, with which a switching function is realized.

Permanently connected to the armature shaft is a magnetic ring, the magnetic field of which permeates the Hall element. When the armature shaft rotates, the magnetomotive-force direction in the Hall element changes. The output transistor is then either switched through or open.

Circuit

Characteristic curves

Hall-effect applications in D.C. motors

By counting the generated output-voltage pulses, one can determine the number of rotations and thus the speed. If the rotational motion is converted into a linear motion, it then becomes possible to monitor the adjustment travel exactly. If there are two Hall generators installed offset to each other at a specific angle α in a motor, then the direction of rotation can also be determined.

They stand for reliable performance, robustness and broad variety of speed/torque. Depending on the model, the rotating speed, rotating angle, position and the torque can be parameterized according to the design.
